VERAE TIME x ZAPIER

Tree nodes and bulk Merkle summaries

<site/docs/02-architecture/tree-nodes.md>

Tree nodes: bulk Merkle summaries vs itemized chain seals

The main Verae chain stores **hash + time + block + certificate**. A Zap that timestamps one document writes that document's SHA-256 as its own seal.

A **batch** of many documents is different: middleware builds a Merkle tree of the item hashes, seals **only the Merkle root** on the chain, and writes each **leaf proof** to external tree-node NATS archives. A later lookup of a member hash will **miss** on the central chain unless the Zap also queries tree nodes.

```
Zapier HTTPS zapper-edge HTTPS middleware
      |
      | Merkle root | verae.archive.put kind=tree
      | (chain seal) | (leaf proof, sharded)
      v
      tree-node-east/west/central
      bloom miss = silence
      ^
      |
      | hash lookup includeTree | verae.archive.query
      | | kinds=["tree"]
      aggregator merges proof + root seal
```

When to use which Zapier search

Search	Hits
Find Timestamp by SHA256	Hash was registered as its own chain seal
Find Hash (tree nodes + central chain)	Chain first, then <code>includeTree=true</code> broadcast

Receipt shape for a bulk leaf

```
{
  "sha256": "<leaf>",
  "exists": true,
  "itemizedOnMainChain": false,
  "merkleRoot": "<root sealed on chain>",
  "proofOk": true,
  "receipts": [
    { "kind": "seal", "of": "merkleRoot", "sha256": "<root>", "certificate": "..." },
    { "kind": "tree-leaf", "archiveId": "tree-node-east", "proof": [...], "leafIndex": 1 }
  ]
}
```

Validate this path in the simulator ([packages/verae-zapier-simulator](#)) before pushing the Zapier app.
